ElGamal encryption is a public-key cryptosystem. It uses asymmetric key encryption for communicating between two parties and encrypting the message. This cryptosystem is based on the difficulty of finding **discrete logarithms** in a cyclic group that is even if we know ga and gk, it is extremely difficult to compute gak.

Idea of ElGamal cryptosystem

Suppose Alice wants to communicate with Bob.

1. Bob generates public and private keys:
    - Bob chooses a very large number **q** and a cyclic group **F**q.
    - From the cyclic group **F**q, he choose any element **g** and an element **a** such that gcd(a, q) = 1.
    - Then he computes h = ga.
    - Bob publishes **F**, **h = ga**, **q**, and **g** as his public key and retains **a** as private key.
2. Alice encrypts data using Bob's public key :
    - Alice selects an element **k** from cyclic group **F** such that gcd(k, q) = 1.
    - Then she computes p = gk and s = hk = gak.
    - She multiples s with M.
    - Then she sends (p, M*s) = (gk, M*s).
3. Bob decrypts the message :
    - Bob calculates s′ = pa = gak.
    - He divides M*s by s′ to obtain M as s = s′.

Public Key generation

alice = Elgamal()

alice_public_key = alice.publishPublicKey()

Encryption

message = "Hello World !"

bob = Elgamal()

bob_cipher = bob.cipher(alice_public_key, message)

Decryption

alice_decrypted = alice.unCipher(bob_cipher)

A Python3 implementation of ElGamal encryption algorithm.

```
from random import randint
from math import ceil, sqrt
